

How to Choose a Good or Bad Power Supply for a Distribution Box

Preview

While power supplies might not be the sexiest components in PC builds, they are one of the most important. In this post, we've given you five things to consider when choosing a power supply for your build. If you take these five factors into consideration, you'll have a much easier time choosing the right PSU for your needs. Power supplies come in a few different standard sizes. The majority of system builders will use a standard-ATX power supply. However, if you're looking to build a mini system, you may need to use a small form-factor PSU. The PSU form-factor you need will be determined by your case. So, make sure you check the spec sheet of the case you want to use. Before you choose a power supply, you need to first figure out how much power you will actually need from your power supply in order to run your computer. You can do this in a couple of ways: 1. Find power draw benchmarks on the components in your system (mainly, your GPU and CPU) and add them together to give you a minimum wattage rating. 2. Use Online. Just because a power supply is listed as a 600W unit (as an example) doesn't mean it can deliver that amount of power over a long period of time. A lot of no-name PSU manufacturers list their power supplies at wattage ratings that are much higher than what they can actually deliver over a given period of time. Some first-time PC builders make the mistake. Testing a power supply is a bit more involved of a process as compared to testing/benchmarking other components. Take a look at the testing methodologies from a site like Tom's Hardware. As you can see, a lot of extra equipment is used in their power supply tests. And, some of that equipment is fairly expensive. And, because the process of testing.
